Sustainable Energy Authority of Ireland
SEAI is Ireland’s national energy authority investing in, and delivering, appropriate, effective and sustainable solutions to help Ireland’s transition to a clean energy future. We work with the public, businesses, communities and the Government to achieve this, through expertise, funding, educational programmes, policy advice, research and the development of new technologies.

SEAI is funded by the Government of Ireland through the Department of Communications, Climate Action and Environment.

Introduction

Welcome to the Community Energy Resource Toolkit. This Toolkit has been developed by SEAI to provide guidance and support to communities interested in developing renewable electricity generation projects in Ireland through the Renewable Electricity Support Scheme (RESS).

The Toolkit is one of many resources which will be developed over time to support communities as part of the Community Enabling Framework, implemented by SEAI. This framework provides end-to-end support to create a community energy sector in Ireland that can flourish and one that will deliver meaningful impact to communities nationwide. For more information on the Framework and supports available please see [www.seai.ie/community-energy/ress](http://www.seai.ie/community-energy/ress).

The Community Energy Resource Toolkit provides a series of practical guidance modules to support project development and delivery, including technology options, business planning, project development stages and good governance. The full suite of guidance modules will be developed in phases, with the first four modules covering the topics of Onshore Wind; Solar Photovoltaics (PV); Planning Process and Grid Connection.

These modules have been designed to provide step-by-step guidance through the process of developing a renewable energy project, from determining your goals, to helping you achieve them. The design of the Toolkit is similar to the Community and Renewable Energy Scheme (CARES) Toolkit which was developed by Local Energy Scotland on behalf of the Scottish Government, to support community and local energy projects across Scotland. These very useful resources have been examined and adapted to an Irish context for Community RESS projects.
How to Use This Toolkit

This toolkit is designed to be used online. Links are **highlighted in blue** and denoted with this symbol: Click on the highlighted text to activate the link.

Navigation buttons are displayed at the bottom of every page. The navigation symbols are:

- Page back
- Page forward
- Jump to next chapter
- Jump to contents page
- Enter full screen mode

What is Solar Energy and How it Works

“In 90 minutes, enough sunlight strikes the earth to provide the entire planet’s energy needs for one year.” – International Energy Agency.

The light from the Sun that reaches the Earth carries energy in the form of radiation. This radiation heats up surfaces and fluids on our planet.

For power production, the light from the Sun can be harnessed in two main ways: through solar thermal technologies, or through solar photovoltaics (solar PV). Solar thermal systems use the light from the Sun to heat up fluids (like water or oil) for either direct use or to create steam that can be used to generate electric power. Solar PV technologies, on the other hand, use solar cells to transform the light from the sun into an electric current.¹

Solar PV has become the most popular renewable technology, with more than 600 GW currently in operation worldwide. Solar PV is the focus of this module.

¹ There are many factsheets explaining how Solar Photovoltaic technology (PV) technology works, for example on the Irish Solar Energy Association or Sustainable Energy Authority of Ireland websites.
Solar PV Systems

The main element of a solar PV system are solar cells. These solar cells rely on the effect of a semi-conducting material (usually silicon) that, when hit by sunlight, creates a voltage difference that, as a result, creates an electric current. Solar panels contain multiple solar cells (usually between 32 and 96).

Solar panels are usually set up in arrays that connect multiple solar panels together. The electricity that comes out of a solar panel or array is Direct Current (DC); this current is constant in time. This is different to the electricity that flows through the power distribution and transmission networks, which is Alternating Current (AC), and varies periodically in time, at a frequency of 50 Hertz in the case of Ireland.

In order to convert the DC produced by a solar panel array to AC required by the power grid, solar PV systems use inverters, which carry out this conversion, and also try to maximise the power output of the array and increase its quality.
Solar Energy in Ireland

Ireland has set a target of meeting 80% of electricity demand through renewable sources and cutting greenhouse gas emissions by at least 30% by 2030 compared to 2005 levels. This will set the path for achieving net zero carbon by 2050. Ireland’s electricity system currently has a 40% renewable share, mainly as a result of the installation of onshore windfarms over the last 25 years. Renewable energy will play a key role in achieving our targets and solar PV is likely to be a strong part of the solution.

So far, Solar PV capacity has seen relatively slow growth in Ireland compared to other countries, but installed capacity is now growing much faster. By the end of 2019, there were 36 MW of installed PV capacity in the country, up from 24.2 MW in 2018. While this is considerably low when compared to other countries (the United Kingdom had over 13 GW of PV capacity at the end of 2019), the rate of growth is still high, showing 50% of compound annual growth in the 2013 – 2019 period.

Figure 2: Decreasing Cost of Solar PV (SEAI/Lazard)
Solar PV costs have dropped dramatically over recent decades and it is now one of the most reliable and low-cost electricity generation sources. Solar cells (and panels) and inverters, which are some of the main components of the system, have experienced significant cost reductions and, thanks to the industry’s growth and maturity, financing, installation and development costs have also achieved reductions. Grid connection costs and long development timelines in Ireland can increase the costs of solar PV, but due to no moving parts and high reliability, the ongoing running costs of solar projects are low.
Solar energy is supported nationally through RESS. This scheme provides financial support for renewable electricity projects of over 0.5 MW in size in the Republic of Ireland. Support is granted through auctions which are scheduled to be held out to 2025 and that allow projects to secure a premium on top of the electricity market price. SEAI offers support to communities on their journey to bid in the community category of RESS auctions.

During the first RESS auction in 2020, solar PV secured support for 796 MW of capacity, more than 20 times the existing capacity. This should strongly support efforts to meet the country’s climate targets and sends a strong signal of confidence in the technology across the country.
Solar PV Development Options and Ownership Structures

Projects can be developed in different ways, each with different levels of involvement, responsibilities and risks allocated to the parties involved. When considering options, it is important for communities to balance risks and benefits. Taking on tasks directly may reduce costs and bring larger benefits but also carries significant risk and responsibilities for the community, while outsourcing and hiring experts may come at a cost but may also significantly reduce risks and responsibilities for communities. Depending on the resources available, some projects may not be feasible, or it can be complicated and risky for communities to undertake the projects, in which case it may be much easier for a developer to do so.

Ownership options

100% of the ownership of community projects must remain within the community to be eligible in the community category of RESS. Previously, in the RESS 1 auction, community projects could be either 100% community owned or community led by way of majority ownership in a joint venture with a developer, however the latter option is no longer supported. Eligibility and ownership requirements for the community category of each RESS auction may vary. We strongly recommend referring to the Terms and Conditions of the specific RESS auction you are aiming for to make sure your project meets all the necessary eligibility criteria.

Development options

The main avenue for communities to develop these projects is by leading and owning the project through all of its development. Alternatively, communities can opt for a shared ownership option, yet under this model, projects would not be eligible for the community category of RESS auctions:

1 Community leads and owns the project throughout all its phases

In this model, the community would lead and oversee all the project stages outlined in this module, acting as the sole project developer. This would mean the community takes on the full commercial, technical and financial risks, but also benefits from potential profits. Community-led projects can avail of support from SEAI to develop their projects. Please visit SEAI’s website and get in contact with us if you think your project is eligible and would benefit from our support.

2 Shared ownership

Shared ownership projects between communities and developers, in which the community identifies the project but shares further costs and risks, are still possible. However, these are only eligible through the commercial category in the RESS auctions.
Overview of Project Development

Phase 1: Developing the Idea
Estimated time: 6-12 months

Step 1: Develop the Vision
Step 2: Seek Advice
Step 3: Initial Viability
Break Point #1
Step 4: Securing Initial Funding
Step 5: Finding a Site
Step 6: Feasibility and Risk Appraisal
Break Point #2

Phase 2: Developing the Project Pre-Planning
Estimated time: 6-12 months

Step 7: Establish a Legal Entity
Step 8: Secure the Site(s)
Step 9: Secure Development Funding
Step 10: Procure Planning and Design Team
Step 11: Grid Application
Step 12: Communicate
Break Point #3

Phase 3: Developing the Project Next Steps
Estimated time: 6-12 months

Step 13: Planning Application
Step 14: Financial Appraisal
Step 15: Initiate Project Construction Funding
Break Point #4
This module presents a series of steps and phases in the development of a solar PV project in Ireland that would be eligible to participate in the government-led RESS auctions. While the module is presented as a sequential and comprehensive series of steps and stages, it is worth noting that, in reality, the process of developing a project may differ greatly from this. This is because timings do not always occur as expected, there may be setbacks and delays during certain steps but, most importantly, because steps should, whenever possible, be taken simultaneously to accelerate the project’s development as much as possible. Developing a project is not a straight path, and it is important to keep a proactive and adaptive approach when going through the process.
The module also considers certain break points, at which it is worth evaluating how the process is looking, to determine whether it is worth continuing with the project. While it is important to maintain momentum and push through obstacles that might appear during the development process, it is also important to set reasonable expectations for the project and its timeline and, possibly, to know when it is best not to move forward with the project.

This module is also complemented by other modules in the Community Energy Resource Toolkit. Please make sure to consult with all other relevant resources of this Toolkit which will help you drive your project forward.
Project – Phases, Steps and Break Points

**Phase 1: Developing the Idea**

*Estimated time: 6-12 months*

Step 1: Develop the Vision
Step 2: Seek Advice
Step 3: Initial Viability

**Break Point #1**

Step 4: Securing Initial Funding
Step 5: Finding a Site
Step 6: Feasibility and Risk Appraisal

**Break Point #2**

---

**Step 1: Develop the Vision**

It is important to understand the reasons for wanting to develop a solar PV project so that your goals can be measured against the eventual outcomes. Not having a clear vision of why you want to undertake the project could lead to undesired outcomes later down the project’s lifecycle. There are many reasons why you may want to develop a solar PV project, including:

1. Becoming energy independent.
2. An interest in the environment and wanting to reduce carbon emissions.
3. Economic drivers that include offsetting energy prices.
4. Developing community cohesion and leadership.

A community action plan is a great way to develop this vision as it specifies the goals the community group wishes to accomplish, the activities required to achieve these goals, the timeline of events and the resources required for it to be successful. Although time and resources are required to ensure all community stakeholders are involved in the process, it essentially guarantees the actions going forward are agreed by the community and, therefore, that any benefits are borne by the community. Some key considerations for an action plan include:

1. What evidence exists around the needs of the community?
2. Categorisation of results – are they optimistic or realistic?
3. Under what timescales are these results achievable (e.g., monthly, quarterly, annually etc)?
4. What are the actions required to achieve these results?
5. Who is responsible for these actions (e.g., the whole community or a particular member)?
6. What are the costs of these actions (e.g., time, monetary, labour etc)?

Considering these steps at the beginning of the project will ensure that activities and outcomes are aligned.
→ **Step 2: Seek Advice**

There are a lot of things to consider when developing a solar PV system. As a result, it is recommended advice is sought as early as possible. SEAI’s Sustainable Energy Community Network, with groups across Ireland\(^2\) is a good place to start. Once you have established a community group, you can join the community network, where a local mentor will be assigned to you to help you set out your aims and ambitions and a group and how best to achieve these.

SEAI also provide regular updates through quarterly newsletters, case studies and upcoming events and webinars to keep you informed and educated on best practices. SEAI will also have support available for communities to develop renewable electricity projects, including support from the SEAI RESS Trusted Intermediary, financial support and access to expert advisors to provide guidance for communities throughout the project development stages, as well as a range of online resources, tools and guidance.

→ **Step 3: Pre-feasibility**

The pre-feasibility or initial viability stage should act as a high-level screening study to determine the suitability of a site. Note that this does not have to be a specific site but should consider the area in which the project is to be developed. This module describes three key factors to consider, and the

1. Local authority zoning
2. Local grid capacity
3. Planning constraints
4. Planning history of solar PV in the local area

**Local Authority Zoning**

Understanding the zoning of local authorities is an important step at the outset of the project. Local authorities grant permission for projects on land within their area. Not all local authorities and their relevant councils have the same policies and guidance relating to solar PV development. Therefore, it is important to examine the local authority development plan and associated zoning maps in the area that you wish to develop a solar PV system to maximise the likelihood of your project being accepted through planning.

**Local Grid Capacity**

Connection to the local energy network is required for projects to come online. It is advisable to investigate local grid networks early to establish broad estimations of local conditions such as:

1. Nearest grid connection point (note connection becomes more expensive and difficult the further away the connection point is from the project site)
2. Current and future limitations on the network (i.e., future developments that will be using any spare capacity within the network region)
3. Costs of connection based on broad estimations of project size, location etc.

Further information on how to estimate local grid capacity can be found in the planning and grid connection modules.

---

Although a more detailed design will be required at a later stage, it is important to understand any local network limitations at an early stage as these can have a large impact on the size, location and cost of a project. A good first source for information for this item is ESB Network’s grid capacity heat maps. These are interactive web-based maps that highlight areas where there is available capacity for additional generation, allowing users to make better informed decisions around where to connect their projects. Please note that, for the community category of RESS auctions, project size must be between 500 kW and 5MW of installed capacity.

Planning Constraints
Planning permission from the relevant local authority is required in respect of renewable energy development unless it is exempted development or is Strategic Infrastructure Development in which case consent is required from An Bord Pleanála. Exempted developments are those developments for which planning permission is not required and are legislated for under Section 4 of the Planning and Development Act 2000 (as amended).

Utility-scale projects, such as those qualifying for RESS auctions, which are the focus of this module, require planning permissions but may be eligible for grid planning exemptions. To avoid any doubt, the development should seek a section 5 declaration from the planning authority confirming the exemption. The relevant Section 5 legislation can be found here.

Most Irish planning authorities have their own guidance addressing the development of solar PV projects and are often open to discussions on development plans. There is a specific public consultation process for each draft county development plan before they are finalised. It is important these are discussed early during the development stage to avoid any possible delays as soon as possible. The planning process module has additional information on planning constraints and important things to watch out for during this step.

Planning History of Solar PV in the Local Area
The planning history of solar PV in the local area can be a useful indicator of the likely success of a new project (i.e. many PV systems may exist locally indicating a welcoming local planning authority). However, the impact of renewable developments is cumulative, and the cumulative impact of surrounding renewables development could still hinder the next development. Therefore, it is recommended that you check the local authorities’ planning history with solar PV, noting any reasons for rejection at the application stage. This will indicate planning issues that solar PV is/has been particularly sensitive to in the local area to avoid for your development.

At this stage, it is advisable (and considered good practice) to reach out informally to local authorities, planners and county councillors to make them aware of the intention to develop the project. This can help identify any additional constraints and could even result in additional support for community projects from these local authorities.
Break Point #1: Does the Project Seem Feasible?

After these steps have been checked, the following step is to reach for initial funds for project development. It is therefore worth considering if the project is likely to move forward – if there is a clear vision, drive and support for pushing the project forward and there are no obvious limitations for construction (such as grid por planning constraints, lack of an appropriate site) – before moving past this stage.

Step 4: Secure Initial Funding

Driving the project through the subsequent development phases may need an investment of roughly 10-15 thousand euros depending on the size of the project. While this is not a challenge for most project developers, it can represent a considerable sum for communities, especially during the early stages of the project considering the risk attached to it.

Communities can opt for private or government grant funding, private loans, community loans or personal contributions (from members of the community or local organisations), or even crowdfunding. The specific type of financing source will largely depend on the resources available, the parties’ appetite for risk and reward and other factors such as interest rates.

Communities should reach out to try to find local sponsors not only for funding, but also other kinds of support they might be able to provide. A local energy agency, for example, may support the project by developing a study, and local authorities could help with planning processes, so reaching out to try to find local sponsors is advisable.

Enablement grants will also be available from SEAI for eligible community groups seeking to develop renewable energy projects. Please visit SEAI’s website for the most up-to-date information on resources available for communities and other ways in which SEAI may be able to support your project.

It is important to keep in mind that the financing should be non-diluting, as ownership of the project needs to remain 100% community-owned, given the regulations established for RESS-2 and potentially all future RESS auctions.
Step 5: Find a Site

After a screening of the local constraints (Step 3: Pre-feasibility), it is time to begin investigating specific sites.

Site
Solar PV systems are versatile and can be installed in a variety of settings such as building integrated (typically on rooftops) and ground mounted. Large, open spaces with minimal shading should be considered as a priority to maximise generation. It should be noted that buildings that fall under the ‘protected structure’ category (i.e., those with architectural, cultural, scientific, historical or artistic interest) will require further investigation of their suitability for building integrated solar PV. The structural integrity of the ground as a mounting structure should also be considered.

Location
The total generation of the system and therefore the financial viability is dependent on the geographical location, orientation, and tilt (inclination) of the PV modules.

Solar irradiation (i.e., the solar resource) varies across Ireland, with the southern regions receiving the most sunlight (the eastern and coastal regions in particular). This is measured on both the number of daylight hours and intensity of the solar irradiation.

As Ireland is in the northern hemisphere, PV systems should aim to face south (180°) to maximise generation with an optimal tilt (inclination) of ~35°. This means that pitched-roofs facing south or near-south often make the best for roof-mounted systems. For ground-mounted systems, a flat piece of land or land with a slight southerly inclination are the most suitable.

A clear, open space with no or minimal shading should be sought to maximise generation from the system. For building integrated systems, areas where nearby trees and other buildings could shade the area designated for solar panels should be avoided. For ground mounted systems, flat and open fields away from vegetation cover with no flooding risk provide the best solution with module rows spaced appropriately to minimise interrow shading.

Access
The site must be accessible both physically and legally to construct and maintain the array. For example, large ground mounted systems require vehicles to transport large pieces of equipment such as racking structures, inverters, and storage containers to the site before they are constructed. It is therefore important to consider access tracks for these vehicles particularly for projects in remote locations. Further, maintenance schedules require multiple visits a year which can be costly if the site is difficult to access.
Step 6: Feasibility Study and Risk Appraisal

The next step should begin to assess the more technical requirements for a project, building on Step 3 (Pre-feasibility) to assess a specific site rather than a general area. This step will assess the technical, financial and regulatory viability for the site(s) and will act as the main technical assessment before applications are put into planning and the network operator.

This may be carried out through any available resources, potentially through an external consultant, and may be informed by suppliers or experienced developers. It is important to have a well-formed view of the typical and site-specific development risks. Seeking experienced advisors is recommended. Key studies will include:
1. Sizing of the PV system
2. High-level planning constraints assessment
3. High-level grid connection assessment
4. Feasibility study
5. Risk assessment

Sizing of PV System
Sizing a solar PV system appropriately is crucial to making the project work financially. This stage will involve assessing various parameters, such as grid capacity, amount of available space, infrastructure needed and optimisation. Additional variables such as permits and studies applicable to plants of different sizes, or the volume of capital that can be raised, may also come into play. The Planning Process and Grid Connection modules have additional information that can help clear some of these items and help communities estimate the size of the PV system.

Planning Constraints Assessment
The planning constraints assessment builds on those presented in Step 3 (Pre-feasibility), investigating planning constraints that may be present at a specific site. Some common planning constraints subject to solar PV developments are the presence of historic objects or overlap with natural reserves.

Further details on this step and on potential planning exemptions can be found on the SEAI website and in the planning process module of this toolkit.

Grid Connection Assessment
This assessment acts as a preliminary assessment before the more detailed grid application in Step 11 (Phase 2). The main aims of this assessment are to:

1. Understand the limitations around the nearest grid supply point.
2. Determine if it is possible to accommodate the proposed system with or without any grid reinforcement works.
3. Determine the likely costs to connect the project to the local grid supply point.

The first step is to identify where the project is likely to be connected to the grid. ESB Networks are the Distribution System Operator for the Republic of Ireland and have existing network capacity maps that can be used to check for the nearest grid supply point.
Following this gathering of information, the final stage is to make an application to ESB Networks with indicative grid connection costs available on the ESB website. Please refer to the grid connection module of this toolkit for additional details and information.

**Feasibility Study**

The feasibility study assesses the financial viability of the project and considers all costs including:

1. **Capital costs** (often referred to as “capex”) which include equipment, installation, development and grid connection costs.
2. **Operation and maintenance costs** (often referred to as “opex”) which includes a maintenance schedule and budget for any reactive maintenance (i.e., maintenance for unforeseen outages or downtime)
   a. Solar panels usually have a 20-25 year lifetime and are commonly warrantied for 10 years for materials and labour, and for 25 years for power degradation
   b. Inverters are usually given with an 8-10 year warranty. Considering the lifetime of the panels, of the RESS contract (typically 15 years), and the project itself, it may become necessary to replace inverters once or even twice, with one of these replacements potentially being covered by the provider’s warranty
3. **Insurance, contingency and rates**

The feasibility study will be informed by things such as cost benchmarks, supplier quotes, and consultant knowledge around planning applications and grid connections to provide you with the likely financial performance of the proposed system (e.g. payback time) and therefore justification as to whether the project should go ahead.

**Risk Assessment**

A risk assessment will be a key part of the feasibility study, detailing a range of risks that the project may face along with the likelihood and severity of these impacts on the project viability. Typical risks would include:

1. **Regulatory or political risks** such as changes to planning guidance preventing project development in a specific area.
2. **Technical risks** such as the inability to connect to the local grid network.
3. **Governance risks** are especially important for voluntary and part-time boards to consider.
4. **Funding risks** such as financing and insuring of the project.

---

**Break Point 2: Is there a Reason to Develop?**

If a feasible site for developing the project has been identified, initial funding has been secured and no major risks or barriers were flagged, then it would be advisable to advance the project to the following stage: developing the project pre-planning.
Phase 2: Developing the Project Pre-Planning
Estimated time: 6-12 months

Step 7: Establish a Legal Entity

Step 8: Secure the Site(s)

Step 9: Secure Development Funding

Step 10: Procure Planning and Design Team

Step 11: Grid Application

Step 12: Communicate

Break Point #3

Step 7: Establish a Legal Entity

It is imperative for the community to establish a legal entity (or use an existing one) to move the project forward. Establishing this legal entity will allow the community to make funding applications, establish financial vehicles, secure sites, make network connection applications, apply for funding, as well as to receive and manage funds.

Once the legal entity has been created, registration for VAT and other applicable taxes should follow, along with the opening of a bank account – while these steps may sound trivial, they can take time, effort and money, and it is advisable to do them early on.

The entity can be established through a number of different legal entities, yet the chosen type of entity must always allow for full community ownership of the project. The community group will need to appoint an accountant and a solicitor to help them choose and form the legal entity that best suits the community. Solicitors will give advice on the legal structure, on land deals, or other substantial contracts that the community may enter. An accountant will help form the legal entity and then support with annual returns, tax returns, VAT returns and other bookkeeping tasks or statutory reporting obligations.

The legal entity adopted by the community must comply with the definition of a Renewable Energy Community as outlined in the relevant RESS auction terms and conditions. For the first auction, RESS-1, requirements for legal entities participating in the community category included:

- Being based on open and voluntary participation, being autonomous and controlled by shareholders or members based or residing in the vicinity of the project.
- Being established as a non-profit or local community organisation.
- The participation of shareholders in the project must not constitute their primary commercial or professional activity.
- The primary focus of the entity must be to provide environmental, economic, societal, or social community benefit to its shareholders or local areas where it operates.

3 Based on RESS-1 Terms and Conditions (T&C’S). For the most up-to-date information, please refer to the T&Cs of the latest RESS auction available.
• Each shareholder or member is entitled to one vote, regardless of shareholding or membership interest.
• The entity or at least one of its shareholders must be registered as a “Sustainable Energy Community” with SEAI.
• Evidence of compliance with the above-mentioned characteristics must be submitted for approval to the Energy Ministry for the Environment, Climate and Communications.

One of the most important aspects will be assuring that the legal entity’s ownership remains 100% community owned, as this will be a requirement for participation in future RESS auctions. Failing to do so would compromise the project’s eligibility for support or benefits from the community category of RESS scheme. It is also crucial to keep the same legal entity name throughout the lifecycle of the project, as any change to this can significantly complicate administrative processes.

If an existing legal entity will be used as a vehicle, it should be reviewed and potentially modified to ensure it covers electricity generation within its activities; new legal entities created for this purpose should contemplate it from the start. Appropriate insurance should also be considered, and appropriate legal protection should be established to protect personal liability.

→ **Step 8: Secure the Site(s)**

Once the legal entity and framework have been established, the site(s) must be secured. This will involve agreements between the project developer and the owner of the site (land for ground-mounted or owner of the building for a rooftop PV system). Although it is largely dependent on the site owner, most will require some form of option to buy or lease the land from them for the operational lifecycle of the PV system. At this stage it is possible that you will enter a formal lease agreement with the site owner, allowing financial close to happen.

This stage includes securing all legal agreements for the use of the site for the project to be delivered and maintained. It is recommended that the feasibility study is carried out before this step, *(Phase 1, Step 6)* to ensure all of the required land rights are included.

---

Step 9: Secure Development Funding

Capital will be needed in order to develop feasibility studies and technical designs, as well as planning and grid connection applications, which are some of the most important milestones in the project’s development pathway.

Securing additional funding therefore becomes necessary at this stage. Given that the project is still in relatively early stages, it may be difficult to secure capital from conventional sources, however, depending on the specific project, funding such as enablement grants may be available depending on the specific project. Communities are advised to visit the SEAI website for information on possible support and other resources.

Step 10: Procure Planning and Design Team

This step involves procuring a professional planning and design team and commencing site appraisals. This step will provide a finalised system design that can be presented to the local planning authority and Distribution System Operator (ESB Networks). This should occur as soon as development funding is obtained as the process can take some time, and it allows risks and issues to be addressed as early in the process as possible.

The feasibility study (Phase 1, Step 6) already investigates some of the potential issues at site from a high-level (i.e. desk-based). This stage builds on the feasibility study by undertaking a formal, finalised system design and site studies rather than the high-level versions likely included previously. Studies would include:

1. Geotechnical surveys assessing ground stability
2. Landscape and visual impact studies
3. Building plans
4. Site visits to accurately model topography and nearby objects for shading analysis in the final design
5. Design and access statement
6. Potential environmental impacts

Once the final system design is completed, the appointed planning and design team will provide you with a range of technical reports forming a portfolio that can be used during the grid and planning application stages.
**Step 11: Grid Application**

It is important to be in contact with the Distribution System Operator as early as possible for a grid application to ensure the project moves along smoothly as it may take some time to secure a grid offer, depending on the volume of connections processed in annual batches. This should happen once the final design is agreed in the feasibility study in Phase 1 (Step 6) and the formal site appraisal (Step 10).

Under the Commission for Regulation of Utilities Enduring Connection Policy process (ECP-2), community renewables schemes fall under their own specified category (category C). Communities must submit a NC5 or NC5A form to the Distribution System Operator which is available on the ESBN website. The form will specify the information required and once an application has been accepted to be processed ESBN will review the connection for the project and if appropriate, undertake a detailed connection assessment for the project. This assessment will detail the methods and costs associated with connecting to the grid. The capacity can be held for two years to allow for other processes to take place such as gaining planning permission. After receiving planning permission and paying the balance of the connection application fee, the project will be given a formal grid connection offer.

**Step 12: Communicate**

It is important to develop projects responsibly, and this includes undertaking consultation with residents and the wider community early in the project and maintaining open lines of communication with them. Communications with stakeholders must be open and honest and establish clearly what the potential impact and benefits of the project might be.

Appropriate time should be allowed for communities, local organisations and residents to provide feedback and engage with the project. This can greatly facilitate moving the project forward, especially in terms of achieving development permissions and avoiding opposition to the project. Some good practices that can be especially effective for this step include:

- Creating a project website, outlining the project, milestones, required work, as well as potential benefits and points of contact.
- Appointing and sharing contact details of a Community Liaison Officer, who would be the communities’ main point of contact and who can attend to the communities’ requests or queries.
- Visiting residences in the immediate vicinity of the project to inform them of the project, sharing information with them (i.e. leaflets), and answering their questions.
- Communicating the construction plans and managing any disturbances that may be caused during the construction stage.

---

• Holding periodic public meetings.
• Reporting on all issues that have been resolved and sharing resolutions with local authorities, community groups and residents.

An important consideration during this step is commercial strategy. There are instances of different communities competing to develop a project in the same location. It is important, therefore, to keep a sensible level of confidentiality and not disclose information that could be harmful for the project whilst also fostering and ensuring community spirit and cohesion is maintained.

→ Break Point 3: Grid Offer Secured and Viable?

It may take some time to secure a grid offer, depending on the volume of connections processed in annual batches. Unless significant barriers or limitations are identified, it is advisable to continue with further steps during this period. If the project secures a grid offer that is financially feasible, then the project can move ahead, but if it is not viable, funding and ongoing activities should cease.
Phase 3: Developing the Project Next Steps
Estimated time: 6-12 months

Step 13: Planning Application
Step 14: Financial Appraisal
Step 15: Initiate Project Construction Funding

Break Point #4

Step 13: Planning Application

All Irish community projects will require a planning application, as the 500kW-5MW range for RESS community projects is beyond the threshold for exemption. A planning application will need to be made to the local authority with all the relevant information collated for examination. An Environmental Impact Assessment is rarely required for solar, being well below the 300MW mandatory threshold. A planning application would usually be accompanied by an Appropriate Assessment screening, usually carried out by an ecologist to assist the planning authority in deciding whether there are negative impacts on any designated Natura 2000 sites.

Despite not requiring an Environmental Impact Assessment, a thorough set of planning assessments and reports will be required covering aspects generally relevant for solar and the planning considerations relevant to the chosen site. Mitigation measures are sometimes recommended if it is determined that the project could have adverse impacts on certain environmental criteria. Further information on this is available from the Environmental Protection Agency and from the National Parks and Wildlife Service.

Once these pre-application studies have been completed, the planning application can be submitted to be reviewed by the Local authority. The local authority will give notice of its decision within 8 weeks of the application, although it may request further information on the application before making a decision. Upon deciding, the local authority will provide a decision notice to the applicant, who can appeal any decisions (or lack of) that the local authority makes to An Bord Pleanála for determination. Third parties that made submissions on the planning application may also appeal the decision to An Bord Pleanála.

If a project is refused at planning, the community group can appeal the decision with further detailed information about the project to support its claim, which should be aimed at addressing the specific reason given for denying the planning consent. The planning process module has additional useful information and guidance on planning appeals. There will be a number of conditions attached to the planning grant which must be fulfilled by the developer of the project, some of which will need to be completed before construction commences.
Step 14: Financial Appraisal

Once the grid connection, which is a significant component of the total cost of a renewable project, has been secured through an offer, and the planning and design costs have been scoped, there will be enough information to carry out a financial appraisal of the project. This appraisal should be undertaken by a suitably qualified consultant or expert. While many of the costs might have been already defined, there will be additional costs and variables still left to determine. It is therefore important to carry out the financial appraisal of the project as thoroughly and accurately as possible with the information available and update it as more costs are defined. Obtaining quotations and contracts will add to the accuracy of the exercise. As a reference, Figure 4 shows the typical composition of the capital costs for utility-scale solar PV plants in Europe. These, however, are typical cost compositions and may vary significantly depending on the specific project.

The scoping of costs should be as exhaustive as possible, covering everything from the most obvious costs (like solar panels and inverters) to the least obvious ones (like those associated with compliance with planning conditions). It should cover all types of costs: from administration and permissions to capital and operational costs. Contributions to the Community Benefit Fund and other legal obligations or expenses should not be overlooked during the analysis.

Figure 4: Cost Break-Down of Utility-Scale PV Projects

Figure 5 illustrates the expected annual cashflows for a 5MW solar farm based on RESS 1 auction result figures and average construction and financing costs in 2021.

An important aspect is the interest rate of the financing to be used for project development, as this will greatly impact the financing costs of the project, and therefore its repayment period and rate of return on the investment. The speed at which the project is developed, and how fast the project can begin selling power through its intended route to market, will also affect these costs. The faster the project is developed, and the faster it can achieve higher rates for its output, the greater the reduction in its financing costs.

Potential lenders will not only look closely at the project financial appraisal – including its forecasted cash flow and balance sheets – and its supporting information but will likely request to see a full business plan covering the expected lifetime of the project.

For additional useful resources on financial modelling, please refer to the Further Information section at the end of this module.

---

8 From an anonymous project. Supplied by Tom Burton, Principal Consultant, BioXL Limited.
→ **Step 15: Initiate Project Construction Funding**

With the financial appraisal complete, discussions on construction funding for the project can be initiated. It is worth noting that financial resources will not be released until the project secures a route to market and reaches financial close – which is explored in Phase 4 and 5 of this module.

Communities can access a variety of funding sources but as mentioned before, funding sources have to be non-dilutive, as projects must remain 100% within community ownership to be eligible for RESS auctions. Communities can therefore opt for project finance, where the project is financed through a loan that is repaid primarily through the project’s generated cash flow, with the project’s assets, rights and interests serving as collateral for the loan.

Communities can also opt for other loan types that may be available, for example by loans from community bodies or members of the community, or by issuing shares to members of the community (although the details of these arrangements will be dictated by the type of legal entity used and the terms and conditions of the RESS auctions), or other finance arrangements, potentially supported by grants or contributions from potential project sponsors.

→ **Break Point 4: Planning Consent Secured?**

If the project has been granted full and final planning permission by the planning authority, then the next step is to find and secure a route to market for the project.

When submitting a planning application, the local authority may request additional information which could lengthen the decision process. Appeals to the decision can be made up to five weeks later – this can result in significant setbacks, with some projects experiencing delays of up to a year.
Renewable energy projects in Ireland can sell their power through three main mechanisms: the wholesale electricity market, corporate Power Purchase Agreements or the government led RESS auctions. Each of these will have its specific set of requirements, deliver different levels of benefit, and pose a different set of risks.

RESS auctions are the best route to market for community projects and should be their primary focus. These auctions allow projects to sell their output at a fixed rate for periods of up to 15 years. This provides a long-term and stable source of income for projects, greatly facilitating securing competitive funding for their development.

Corporate PPAs can also provide a stable source of income, but they are usually shorter in term compared to RESS contracts, and they also pose off-taker risk (will the power buyer remain in operation and demand the agreed amount of power for the duration of the contract? Are they credit worthy?) and, in some cases, operation and maintenance risk associated with power infrastructure.

The wholesale market, due to its uncertainty, volatility, risk, and its relatively low prices, is not a desirable long-term source of income for renewable projects. Depending on this as a source of income can be a major obstacle to securing project financing.

---

**Step 16: Qualify for Market**

As soon as it is possible, communities or project administrators should prepare the necessary documentation, permissions and other requirements to be able to bid for the chosen route to market. For both tendered or auctioned corporate PPAs and RESS auctions, requirements are published well in advance, giving potential bidders enough time to prepare their applications and fill any gaps that the project might have in order to be eligible for bidding.

For RESS auctions requirements, it is advisable to stay up to date with announcements from the DECC and thoroughly review the Terms and Conditions of the auction.

Securing the route to market is crucial for the project’s financial success. Starting this process with enough anticipation and dedicating sufficient resources is therefore paramount.
Step 17: Bidding in Auctions or Tenders

RESS auctions are expected to be the main route to market and the safest source of income for communities developing renewable energy projects in Ireland. These auctions are held periodically and aiming to secure contracts in these tenders is key for communities, as the project is expected to receive low returns on their output if selling directly to the market (which will be the case from the moment the project begins operations until the RESS contract or the PPA kicks in).

Pricing strategy is also an important part of the process. The first RESS auction was competitive and, while only one community project did not get awarded with a RESS contract, future auctions are expected to be oversubscribed (i.e., there will be more capacity bidding for contracts than there is capacity to allocate in the auction), which will intensify competition.

Information and analyses gathered during the financial appraisal and modelling of the project will be key in this step. A thorough analysis of project costs, along with sensible reflection on the realistic returns that can be expected from it, are key inputs that will inform the decision of how much to bid during the auction. These can be challenging steps, but they are key to the project’s success. The results from the first auction, RESS-1, can be accessed [here](#), showing that community projects achieved a weighted average strike price of 104.51 €/MWh. Please note, however, that an increase in competition in future auctions and the reduction of technology costs may drive achievable strike prices down for future auctions.

It is therefore advisable for communities to prepare timely and diligently to bid in these auctions. SEAI provides extensive guidance and support to communities and guides them through the journey to the bid.

For more information on SEAI’s support please visit [this link](#). Additional queries on the auction or its requirements can be directed to [DECC](#) or [Eirgrid](#).

Break Point 5: Route to Market Feasible?

If the project has obtained a RESS auction contract, or a long term Power-Purchase Agreement through which it can sell its power at a stable rate, then it is advisable for the project to progress into the following stages of financing.
Phase 5: Getting to Financial Close
Estimated time: 6-12 months

Step 18: Procurement
Step 19: Development Management
Step 20: Senior Lender and Equity and Subordinate Finance
Step 21: Financial Close

Break Point #6

Step 18: Procurement

The procurement phase involves finalising the scope and amount of all quotations and confirming and engaging with the suppliers and installers to be used to deliver the solar PV system and all associated works. This is a crucial stage to ensure that the delivery and management of the project throughout its lifecycle are delivered in a timely and efficient manner.

A detailed scope and documentation pack will be needed, and is typically put together by the owner’s engineer who runs tender process(es) for the main project components, typically the solar installation and the grid connection works.

It is highly recommended to seek tenders from multiple installers and contractors to ensure competitiveness and a cost effective solution. Although the cost of PV modules is often the single biggest expense, it is also important to examine other costs and benefits associated with different contractors including warranties, cost and frequencies of maintenance schedules etc.

Once the community group have chosen an installer within the tendering process, the appointment of an Owner’s Engineer is recommended. The Owners Engineer is essentially a representative, appointed by the community group to ensure that work is done within the technical and legal specifications and requirements. The Owner’s Engineer communicates with the community group directly to report progress. This allows a technical expert to oversee the project delivery, thus reducing the strain on the community group who may not be familiar with delivering such a technical project.

With contractors confirmed, the community group can work with the selected Owner’s Engineer and suppliers/installers to select, in detail, the most appropriate equipment for the solar PV system accounting for budget, desired generation, detailed design, planning responses from local authority on location wand size of the system etc.
Step 19: Development Management

Many ongoing development tasks occur during this phase associated with the critical implementation steps to progress the project commercially and technically. A wide range of professional support will be required for this phase.

Examples of complex tasks or negotiations that typically occur during this phase are given below. These steps will also be a pre-requisite of financial close.

- A Power Purchase Agreement (PPA) is required to provide an interface with the Single Electricity Market and electricity customers. A market maker with a strong balance sheet is typically required here, to ensure that all funds are secure at all times and come back to the community-owned generator. Some communities may wish to set up different versions of this, for example setting up a parallel electricity supply company (known as “Supplier-Lite”) which is dedicated exclusively to trading the power of the community-owned generator. The typical function of the PPA provider is shown in the diagram below:

Figure 6: Arrangements and Interactions with PPA Provider and the Single Electricity Market Operator
• **A planning decision** will usually come with a series of conditions which often involve detailed pre-construction tests or studies, such as archaeology tests or ecological surveys which will take time and funding to address prior to construction. There can be timing consequences. For example, where a field is in crops, archaeology testing can only be carried out under license, after the crop is cleared. During the process, it may become necessary to submit amendments through the planning process, where a design is not compliant with the consented solar farm. This can happen, for example, due to a change in regulations, or due to obsolescence of the original design because of changes in the surrounding infrastructure.

• **A grid connection** requires ongoing management and interaction with ESB Networks and other stakeholders. Sometimes it is necessary to apply for planning consent for the grid route (separately to the solar farm). A road opening license from the local authority may be required and engagement will be needed with the area engineer for the local authority. Detailed designs need to be prepared and submitted to ESB Networks for approval. ESB Networks request 12 months’ notice on certain design items to plan the connection. Stage payments will need to be made to ESB Networks as the project advances.
Step 20: Senior Lender and Equity and Subordinate Finance

Typically, a renewable energy project will require project finance from a senior lender (usually a commercial bank) to provide circa 80% of the overall capital requirement on a long term loan. This is a detailed commercial step which will require financial modelling, due diligence and complex contract drafting and negotiation.

Legal, technical and financial advisors are required to support this key item which is the most important element of financial close. All suppliers, contracts and shareholder arrangements will be carefully scrutinised.

The schematic below shows a typical range of contractual relationships that the legal entity will have entered into.

**Figure 7: Typical Range of Contractual Arrangements that the Legal Entity will Need to Establish**
**Step 21: Financial Close**

Financial close is the milestone where 100% of the funds required to complete the project are committed and the project can be constructed. This will typically entail rigorous due diligence and legal agreements.

In addition to a senior lender there may be additional equity, grant or loan funding required before the final decision is made to progress with the construction and draw down on funding sources. Detailed agreements will be required for any equity or loan providers who typically sit below the senior lender in priority for payments.

**Break Point 6: Did the Project Reach Financial Close?**

If the project has reached financial close, that means that all the most important milestones in the development phases have been cleared – the project now has a green light for starting construction.
Phase 6: Completing the Project
Estimated time: 6-12 months

Step 22: Construction

Step 23: Community Benefit

Step 24: Operation

Step 25: Governance / Management

Step 26: Decommissioning

Step 22: Construction

Construction of the project and connection to the grid can begin once all the aspects of planning and development have been addressed. This includes:

1. Gaining planning permission from the local authority based on the finalised design, location, and size of the system.
2. Finalisation of the project financing.
3. Land agreements have been executed.
4. Grid connection agreement in place.

With these permissions in place, the construction (also referred to as installation) of the solar PV system can commence.

Two contractors are typically required for the installation of the solar system. These are the EPC (engineering, procurement and construction) contractor and the Grid contractor, both of which are overseen by an Owners Engineer. The Owners Engineer is a representative, chosen by the community group, typically from the commissioning company (the company responsible for assuring that all systems and components of a building or industrial plant are designed, installed, tested, operated, and maintained according to the operational requirements) for the project. The EPC contractor is responsible for all the installation processes apart from the connection to the grid, including:

1. Preparation of site (e.g., ground engineering works)
2. Purchase and delivery of equipment to the site
3. Final installation of the equipment

Once the EPC contractor has completed the installation of the project, the Grid contractor can connect the system to the local Grid supply point, install a meter and the local planning authority can be notified of the completed development.

The Grid contractor must be a Registered Electrical Contractor.
**Step 23: Community Benefit**

Prior to beginning commercial operations, projects are required to establish a Community Benefit Fund, under the RESS-1 Terms and Conditions, which currently establish the required contribution at 2 €/MWh of power output per annum (adjusted by losses, considering both transmission and distribution losses, which is determined by the Transmission System Operator and Distribution System Operator).

This fund will be aimed at providing additional environmental, social and economic well-being to the local community, and will be registered in a national register, which can be found [here](#).

A Fund Committee, consisting of volunteer community representatives, and the project administrator and developer, needs to be established. A small part of the fund (<10%) can be used to cover administration expenses. Communities should participate in all decisions around how the funds are used, for example, for retrofitting homes to increase their energy efficiency.

It is the responsibility of the community and/or developer developing the RESS project, as well as of administrators to promote and inform about the availability of financial support from the Community Benefit Fund, by issuing notices in local newspapers, delivering notices to local residents, promoting it through websites and social media, contacting community and voluntary organisations, or other means available. Administrators will also be responsible for assessing all applications to resources from this fund in a non-discriminatory and transparent manner and report this information to SEAI. SEAI will have oversight over the funds and ensure compliance of the fund and its management. A report on the management and disbursements of the Community Benefit Fund must also be submitted annually to SEAI.

For more information on this topic, please refer to the Good Practices Principles Handbook, which was published in July 2021 following a review of a public consultation on the topic. For more reference on this, please visit the DECC website to access the finalised [Handbook](#).

Additional provisions on these funds can also be found in the Terms and Conditions of the respective RESS auction.

**Step 24: Operation**

The project will need to have a maintenance schedule in place to maximise system performance and financial returns. Maintenance usually comes in two forms undertaken by a contractor: a Planned Preventative Maintenance schedule and reactive maintenance. Planned preventative maintenance activities include:

1. Module cleaning
2. Inverter checks
3. Vegetation management
4. Racking system checks

---

According to the DECC’s Good Practices Principles Handbook for Community Benefit Funds
Reactive maintenance (or unplanned maintenance) are activities which react to sudden events such as downtime from inverter failures. A comprehensive planned preventative maintenance schedule however can largely negate the need for reactive maintenance. Communities can monitor the system remotely using specialised monitoring software with a user log in that can be provided by the operation and maintenance company if desired.

Revenue streams should be managed in accordance with conditions laid out with the funder of the project. The fixed costs that the project incurs (e.g. land rent, CBF contributions, loan repayments and maintenance contracts) should be paid first with the remaining income then distributed between the members of the community group.

Due to the numerous activities associated with operating and maintaining a solar PV system, it is advised that the community group arranges regular meetings (e.g. monthly or quarterly) to review the project. This could include feeding back to members on recent maintenance visit findings or to flag issues that may be arising (e.g. Topics discussed at such meetings could include updates on operations and maintenance, budget reporting, allocating of profits and community benefit fund updates).

Step 25: Governance / Management

The project will require formal and diligent management through its operation stage. This should cover all aspects of the project: collecting and distributing income, meeting operating standards, and overseeing the operation and maintenance of the plant to make sure that equipment is being monitored, repaired and replaced when needed.

For effective management, and to ensure that the project and its funds deliver the benefits they are intended to, it is important to agree on a vision, purpose, mission and define the organisations’ values, and following them consistently. Developing, resourcing, monitoring and evaluating plans that follow these objectives can greatly aid in the governance and management of both the project and its funds. When developing these plans, however, it is important for communities to set realistic expectations and effectively allocate responsibilities.

Stakeholder agreements are a key part of governance and management of the project and its funds and can be a way to future-proof the entity. These were probably already in place before reaching the operation stage, as they are usually needed to access funding. These agreements must be followed and upheld to guarantee a smooth governance of the project and its funds through the project’s lifetime.

As outlined in Step 23, governance and management should also cover the evaluation and sanctioning of disbursements of the Community Benefit Fund; this responsibility also extends to any surplus funds generated by the project. Surplus funds management should be done according to the best practices available, and adhere to the Governance Code for Community, Voluntary and Charitable Organisations of Ireland. An annual Community Benefit Fund report must be submitted annually to SEAI. The Environmental Protection Agency and The Wheel have developed a guideline document titled “Sustainable Communities: A governance resource book for small community and voluntary organisations”, with a very comprehensive guide and resources to carry out responsible and transparent governance of these types of organisations.
The Governance Code for Community, Voluntary and Charitable Organisations and Toolkit of the Charities Regulator of Ireland outlines the minimum standards that should be met to effectively manage and control charities, and provides resources to do so.

This should be done in a fair and transparent manner, seeking to deliver economic, social and environmental benefits to the communities in the vicinity of the project, and fairly address the interests of the legal community entity that owns the project.

**Step 26: Decommissioning**

At the end of the project lifecycle (typically 25-30 years), the PV array is likely to require removal from the site. If the project is a permitted development (i.e., it required planning permission to be developed), then decommissioning should take place to the timescales proposed within the planning consent, accounting for all practicalities.

Recycling and appropriate waste management during this process are highly important. Both main types of solar panels (silicon-based and thin-film based) can be recycled through industrial processes and their disposal is regulated at EU-level by the Waste Electrical and Electronic Equipment Directive. Up to 95% of the glass in solar modules, as well as external metals, can be reused.
Further Information

→ Solar Development

The following websites provide general information for communities with an interest in solar PV:

<tbody>
<tr>
<td><strong>Alternating current (AC)</strong></td>
<td>A type of electrical current whose magnitude and direction varies cyclically in regular intervals (in Ireland, the frequency of change is 50 Hertz).</td>
</tr>
<tr>
<td><strong>Balance of system</strong></td>
<td>Represents all components of a PV system other than the panels and inverters.</td>
</tr>
<tr>
<td><strong>Community benefit fund</strong></td>
<td>Fund established to be used for the wider environmental, social and economic well-being of the local community.</td>
</tr>
<tr>
<td><strong>Direct current</strong></td>
<td>Electric current with a constant voltage that travels in a single direction.</td>
</tr>
<tr>
<td><strong>Distribution System Operator</strong></td>
<td>Entity that manages a network that takes energy and transfers it from high-voltage transmission systems to the distribution system and then to the final customer.</td>
</tr>
<tr>
<td><strong>Electrical grid</strong></td>
<td>An integrated system of electricity distribution, usually covering a large area.</td>
</tr>
<tr>
<td><strong>ESB Networks</strong></td>
<td>Distribution System Operator of Ireland.</td>
</tr>
<tr>
<td><strong>Feasibility</strong></td>
<td>Condition in which something is achievable, executable and/or practical.</td>
</tr>
<tr>
<td><strong>Generator</strong></td>
<td>Person who is the holder of a licence and any other legal requirement to generate electricity.</td>
</tr>
<tr>
<td><strong>Greenhouse gases</strong></td>
<td>Gases that absorb energy in the form of radiation (such as sunlight), and later emit it in frequencies that – completely or partially – cannot go through the atmosphere, causing the greenhouse effect.</td>
</tr>
<tr>
<td><strong>Grid Code</strong></td>
<td>The conditions, procedures, provisions and codes governing the planning and operation of the transmission system and the scheduling and dispatch of generation prepared by the pertinent authority.</td>
</tr>
<tr>
<td><strong>Installed capacity</strong></td>
<td>Total output capacity of a plant, measured in kW or multiples (MW, GW…). For solar PV plants, this is defined as the output capacity of the inverters.</td>
</tr>
<tr>
<td><strong>Inverter</strong></td>
<td>A device that converts direct current electricity to alternating current. In the case of PV systems, it also performs output optimisation to maximise the amount of energy that is harnessed from the solar array.</td>
</tr>
<tr>
<td><strong>Kilowatt</strong></td>
<td>Unit of power – or rate of consumption / generation of energy – equivalent to one thousand Watts, usually used in power generation to measure or indicate the maximum capacity of a plant (e.g., a 500 kilowatt plant was installed at the site).</td>
</tr>
<tr>
<td><strong>Kilowatt-hour</strong></td>
<td>Unit of energy, equivalent to using or generating one kilowatt for one hour.</td>
</tr>
<tr>
<td><strong>Photovoltaic array</strong></td>
<td>Group of solar panels interconnected in series.</td>
</tr>
<tr>
<td><strong>PPA (Power Purchase Agreement)</strong></td>
<td>Agreement in which a power producer agrees to sell – totally or in part – its power output to an off-taker under a certain price and/or set of conditions.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>RESS 1</strong> (Renewable Energy Support Scheme 1)</td>
<td>The first RESS competition and includes the RESS 1 Auction and the RESS 1 Support.</td>
</tr>
<tr>
<td><strong>SEAI</strong></td>
<td>The Sustainable Energy Authority of Ireland.</td>
</tr>
<tr>
<td><strong>SME</strong></td>
<td>A micro, small or medium-sized enterprise as defined by the appropriate law and statutes.</td>
</tr>
<tr>
<td><strong>Solar panel</strong></td>
<td>Group of solar cells ensembled in a single, flat unit, ready for use. Since it is made of solar cells, it also creates a voltage difference when hit by sunlight, which can be used to create an electric current.</td>
</tr>
<tr>
<td><strong>Solar PV (photovoltaic)</strong></td>
<td>Technology for electric power generation that relies on radiation from sunlight and the photovoltaic effect of certain materials to provide electric power.</td>
</tr>
<tr>
<td><strong>Solar radiation</strong></td>
<td>Energy provided by the sun in the form of radiation that can be used by solar PV technologies to provide electric power.</td>
</tr>
<tr>
<td><strong>Solar cell</strong></td>
<td>Elemental piece of solar panels which, when hit by sunlight, creates a voltage difference that can be used to create an electric current.</td>
</tr>
<tr>
<td><strong>Supplier</strong></td>
<td>Entity licensed by the Regulatory Authority to supply electricity in Ireland.</td>
</tr>
<tr>
<td><strong>Sustainable Energy Community</strong></td>
<td>A “Sustainable Energy Community” which is registered as such with the SEAI.</td>
</tr>
<tr>
<td><strong>Transmission System Operator</strong></td>
<td>“Transmission System Operator” means EirGrid plc in its capacity as transmission system operator pursuant to a licence granted by the Regulatory Authority</td>
</tr>
