## Our history

Since our founding, we've been at the forefront of the green building movement, constantly researching and developing new systems that meet the needs of our customers and the planet.

Ecological's parent company is MacCann & Byrne, a family-owned hardware and timber company steeped in history that has been established on the same premises in Athboy since 1906.

1906

Our parent company, MacCann and Byrne, is founded in Athboy, County Meath.

Our parent company, MacCann and Byrne, is founded in Athboy, County Meath. McCann and Byrne successfully trade as an independent hardware merchant supplying hardware and timber products to the Irish market. The company remains family owned to this day.

- **1906** ✓  
Our parent company, MacCann and Byrne, is founded in Athboy, County Meath.
- **2000** ✓  
Ecological Building Systems launched as a subsidiary company of MacCann and Byrne.
- **2007-2008** ✓  
Ecological Building Systems launch in the United Kingdom.
- **2009** ✓  
Centre of Knowledge launched in Athboy.
- **2013** ✓  
UK offices and warehouse are moved to Carlisle, Cumbria
- **2020** ✓  
Re-launch of [ecologicalbuildingsystems.com](https://ecologicalbuildingsystems.com).
- **2022-2023** ✓  
Ecological Building Systems in Ireland becomes an independent limited company

1 in 6 Irish buildings are solid walled  
>7 million in the UK

# Moisture And Its Impact On Building

**Ill-considered** retrofits will often result in moisture related damages such as;

- **decay** of bricks due to freeze-thaw,
- structural **rot** of timber joists,
- condensation in attics leading to roof **failure** or,
- **mould** growth at **cold** surfaces, which is a potential **health risk** for occupants

“Except for structural errors, about 90 percent of all building construction problems are associated with water in some way”  
(ASHRAE, 2011)

# Moisture And Its Impact On Building

Thermal solutions must account for the local climate...especially when upgrading single leaf masonry walls.

- Context:** understanding the building's history, setting, construction, condition, occupancy pattern, etc.
- Coherence:** adopting a consistent, integrated, whole-building approach to all aspects of new-build and retrofit.
- Caution:** identifying, assessing and managing moisture risks, and, where knowledge is limited, erring on the side of caution.
- Capacity:** ensuring adequate capacity in building systems rather than over-optimising, to allow for unexpected or changing circumstances.

Not to scale

## Primary drivers of moisture ingress

- External Climate  
(wind driven rain, snow, frost, humidity)
- Internal moisture  
(Cooking, washing, plants, etc)
- Built in moisture within building materials
- Ground source damp

# In New Build Or Retrofit A Building Should Be Seen As A System

# Impervious Non-breathable Insulation Can Result In Similar Symptoms

# Impervious Non-breathable Insulation Can Result In Similar Symptoms

Figure 17: Problematic stud and batt interior retrofit with imperfect airtightness

DOE/BSC

Controlled Ventilation is an important step in any whole building approach to retrofit

Unplanned air movement can cause poor thermal comfort, surfaces become cooler & the risk of condensation and mould is increased

# What are the ventilation options?

Mechanical systems can be designed to extract air from the building allowing it to be drawn in through vent openings. Some systems simply push air out of the building through openings

Demand Controlled reacts to air quality parameters like CO<sub>2</sub>

Some systems work by moving balanced volumes of air in (supply) and out (extract) with single room heat recovering units centrally controlled to work in pairs (ductless).

Decentralised systems avoid duct networks in complex retrofit and achieve impressive heat recovery

Some systems achieve the same balanced volume of air in (supply) and out (extract) with using a ducted network of pipes returning to a central heat exchange unit.

Centralised systems are planned carefully with new builds and must be in place for airtight buildings

Natural Systems respond to pressure differential across a building envelope generated by wind forces and temperature differences both inside and outside.

Cross flow natural or Stack ventilation can be a useful hybrid approach to offset overheating risk... even UK & Ireland are getting warmer!

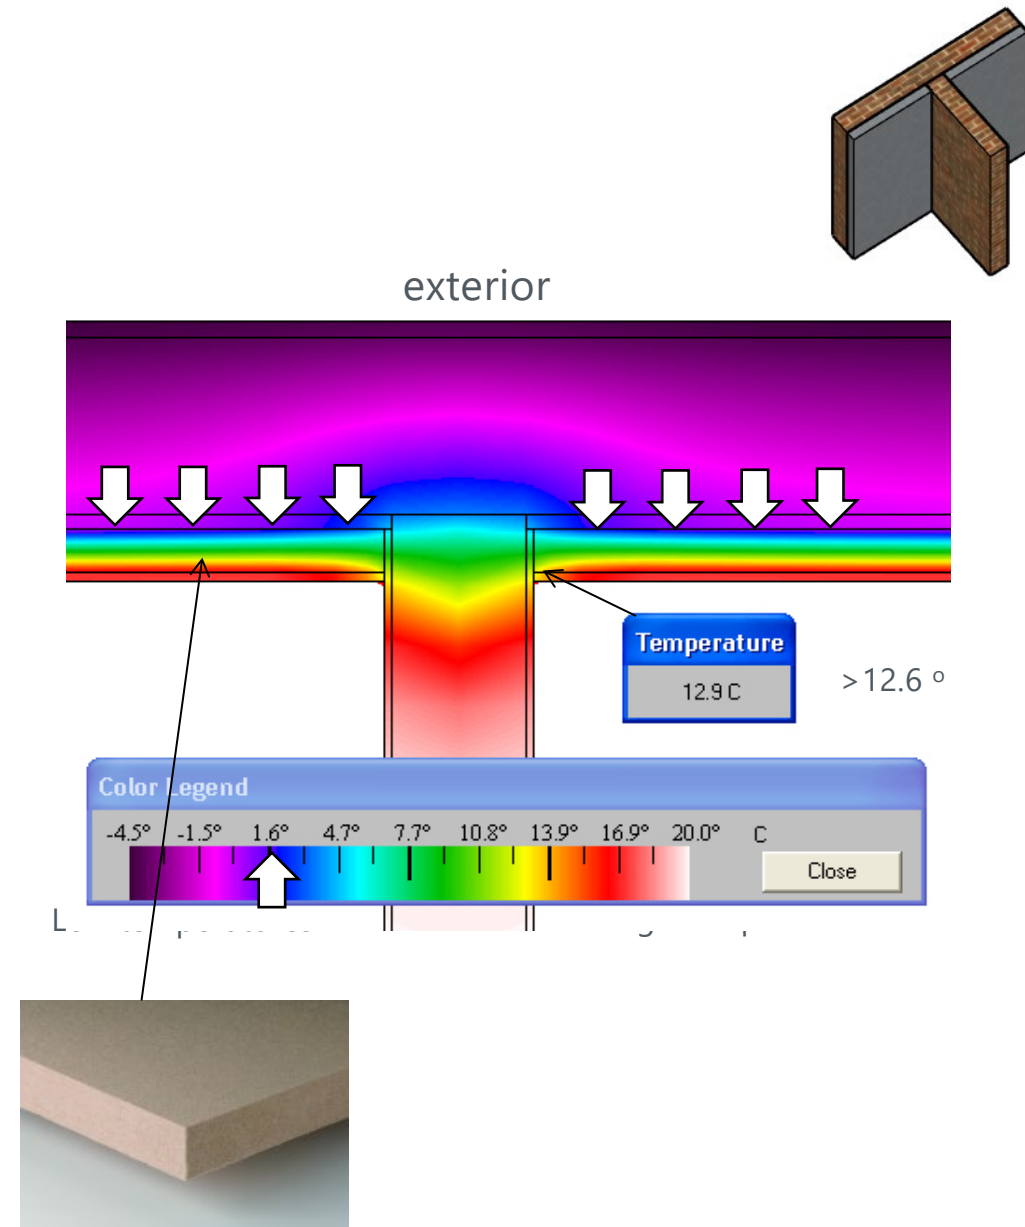

# Thermal Bridges

A break in the continuity of the thermal insulation with a material with a higher thermal conductivity

## Moisture and its impact on Buildings

Solid masonry Internal wall meeting un-insulated external wall

Figure 51: Woodfibre insulation board being prepared prior to application of finish coat

Figures 52 and 53: Insulating cork lime plaster sprayed on an uneven wall with reinforcement mesh applied below finish coat (Photographs by Con Brogan for OPW)

*“Any measures that would present unacceptable hygrothermal risks should be excluded from the short list of measures.”*

# Latest Guidance From Irish Government

- The method for calculating U-values of building elements and components is specified in I.S. EN ISO 6946:2017.
- The method for calculating U-values of components involving heat transfer to the ground, e.g. ground floors and basement walls, is specified in I.S. EN ISO 13370:2017.
- Further guidance on calculating U-values and a list of default values for common building materials can be found in Appendix A of TGD L.
- Thermal modelling of documented wall build-ups showing the combination and proportion of specific known Department of Housing, Local Government and Heritage 2.3 Potential Health Risks materials (e.g. lime mortar, limestone, air) can also be used to derive U-values in accordance with I.S. EN ISO 6946:2017.
- Where in-situ U-value assessment is undertaken, it should be done in accordance with ISO 9869-1:2014. However, in the absence of acceptance of the ISO 9869 methodology by the European Commission, in-situ U-values are currently not an acceptable source of data for demonstration of compliance with TGD L or for use in BER calculations.

# Latest Guidance From Irish Government

## Complying with Regulations

Any materials used should comply with Parts D and L. TGD D defines proper materials as materials that are fit for the use for which they are intended and for the conditions in which they are to be used, and includes materials that:

- bear a CE marking in accordance with the provisions of the Construction Products Regulation
- comply with an appropriate harmonised standard or European Technical Assessment in accordance with the provisions of the Construction Products Regulation, or
- comply with an appropriate Irish Standard or Irish Agrément Certificate or equivalent with an alternative national technical specification of any state that is a contracting party to the Agreement on the European Economic Area, which provides in use an equivalent level of safety and suitability.

*For traditional buildings, it is generally recommended that vapour-open insulations be used to minimise the risk of surface and interstitial condensation.*

*Extruded polystyrene (XPS) and polyurethane rigid foam (PUR)/polyisocyanurate (PIR) have a high vapour diffusion resistance factor, meaning they inhibit moisture from moving through them, which may retard the evaporation of interstitial condensation.*

# Latest Guidance From Irish Government

## Product approvals and compliance with Construction Product Regulations

**DIASEN**  
GREEN BUILDING FUTURE

**DECLARATION OF PERFORMANCE** CPR-122/2020 DP001EN20442606

1. Unique identification code of the product-type: Diathonite Evolution.  
2. Intended uses: Designed general purpose rendering/plastering mortar for external and internal use on walls, ceilings, columns and partitions.  
3. Manufacturer: Diasen Srl - zona Ind.le Berbenzina, 5 - 60041 Sassoferrato (AN) - [www.diasen.com](http://www.diasen.com)  
4. Systems of AVCP: System 4.  
5. Harmonized standards: EN 998-1:2016.  
6. Notified bodies: No tasks for the notified body.  
7. Performances declared:

Essential characteristics	Performances
Reaction to fire	Class A1
Water absorption	0.4 kg/m <sup>2</sup> /min <sup>1/2</sup>
Water vapour permeability	$\mu = 4$
Adhesion	$\geq 0.10 \text{ N/mm}^2$ - FFP B
Thermal conductivity ( $\lambda_{0.05}$ )	0.043 W/m·K
Durability	NPD
Dangerous substances	See SDS

The performance of the product identified above is in conformity with the set of declared performances.  
This declaration of performance is issued, in accordance with Regulation (EU) No 305/2011, under the sole responsibility of the manufacturer identified above.

## Novel materials mixed on site

This Information Paper provides a broad view of the benefits and limitations of non-loadbearing hemp lime walls for those considering their use in construction projects.

Hemp lime is a low-carbon building material with good insulation properties and robustness. It is particularly suited to projects where the design calls for a rendered or rain-screened external finish, good insulation and minimal thermal bridges. It is most commonly used in conjunction with timber frames, but can act as a non-structural walling element for a variety of construction types, including lining masonry walls.

This is one in a series of five Information Papers and parallel case studies on low-impact building materials. The others cover straw bale, unfired clay masonry, cross-laminated timber and natural fibre insulation.

Hemp has been used for millennia in a wide range of applications, from sacks and rope through to paper and oil. It was one of the first domesticated plants (originally in China) and was a sufficiently important material that it was taken to America in seed form by the Pilgrim Fathers.

Industrial hemp is now grown again in Europe and North America, having been banned for a period due to the connection with cannabis (industrial hemp has very little active drug). It can be grown in many temperate climates, and in the northern hemisphere is usually planted in April and harvested at the end of August. Hemp is a fast-growing plant, reaching a height of 3–4 m at harvest with no need for pesticides or herbicides after planting. Once harvested, cut hemp is sometimes allowed to dry initially in the field before the shiv (the woody central core) is separated from the outer fibres. The fibres are extracted for a variety of uses (e.g. textiles, composites). After fibre extraction, the shiv is shredded into chips, graded and stored until required for construction.

Figure 7: The Renewable House on the Innovation Park at BRE near Watford, Herts, constructed with hemp lime walls (Courtesy of Lime Technology)

When used in situ, hemp lime is applied as a non-structural external infill; it is typically cast inside formwork. Alternatively, it can be spray-applied against a lining board. Both methods result in a homogeneous solid wall construction encapsulating a timber frame that has good insulation properties and good airtightness, and avoids thermal bridges.

Hemp lime is most commonly a mix of renewably sourced hemp shiv, a specially formulated lime binder and water. Hydraulic lime (as opposed to hydrated lime), which is able to set and harden under water, has been used in place of formulated binders, with the mix created independently, although performance can be less reliable as a result. A proportion of cement is usually added to formulated commercial binders to aid the early age performance. The quantity of cement used varies between producers and in many cases has not been disclosed. However, the addition of pozzolanic material such as pulverised-fuel ash in many formulated limes minimises the use of cement.

# Responsible retrofit of traditional buildings

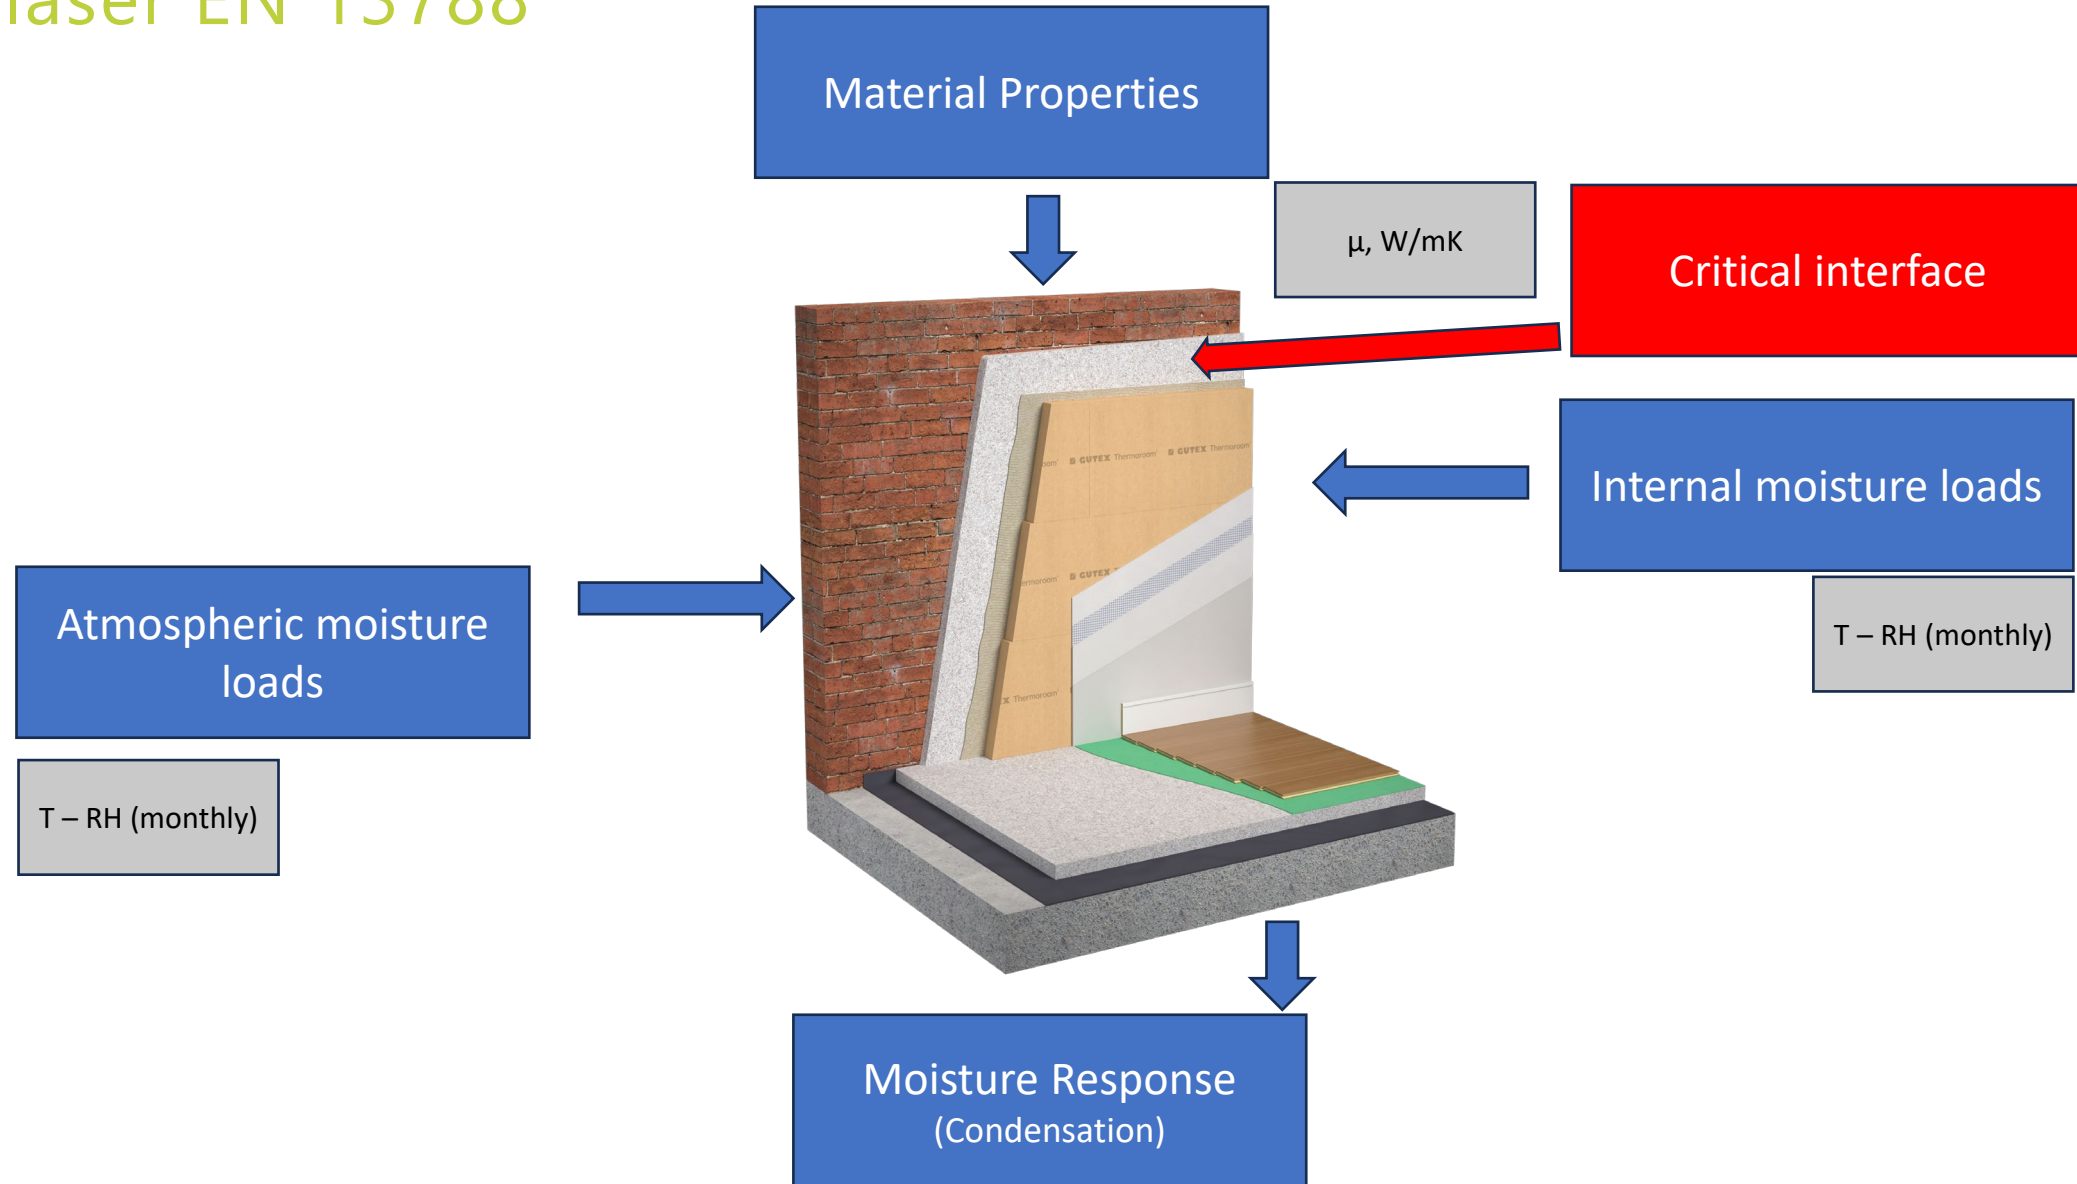

- EN 16883:2017 Conservation of cultural heritage - Guidelines for improving the energy performance of historic buildings
- Requires a first phase of recognition of the significance and specific values of the construction based on which unsuitable measures should be excluded from the intervention design.
- Modern buildings designed to block moisture entry (i.e. capillary breaks , membranes to reduce vapour diffusion, vented cavities, etc)
- On the contrary traditional building are largely characterised with walls which absorb, buffer and then dry out thanks for their inherent vapour permeability, capillarity etc.
- Great care is needed to ensure the chosen thermal solution does not compromise this cycle leading to degradation and moisture accumulation.
- Buildings are like fingerprints, with no two the same and the thermal solution must be carefully considered.

Material Information - Hygrothermal Functions

Insulation plaster  
Thickness: Up to 4 cm (1.6 inches)

Manufacturer's notes:  
Diathonite Thermactive.037 is an eco-friendly Exterior Insulation Finishing System - EIFS, whose main ingredients are granulated recycled cork, expanded amorphous silica, perlite and pumice combined in a balanced particle size distribution curve (0 - 3 mm / 0 - 0.12 in). Natural hydraulic lime NHL 5 is also present in the compound, therefore the product is antibacterial and prevents the formation of moulds and fungi. Diathonite Thermactive.037 is a highly porous, light-weight, breathable, thermal insulation plaster; it has an excellent fire reaction performance (non-combustible); it is not damaged by dampness and it is recyclable as an inert at the end of its life cycle. This thermo-plaster offers a versatile, monolithic and highly resistant solution to protect buildings from

# Hygrothermal Modelling And Its Role In Assessing Risk

BS EN 15026:2023

BS EN 15026:2023  
EN 15026:2023 (E)

## Introduction

This document defines the practical application of hygrothermal simulation software used to predict transient heat and moisture transfer in multi-layer building envelope components subjected to dynamic climate conditions on either side.

In contrast to the steady-state assessment of interstitial condensation by the Glaser method (as described in EN ISO 13788), transient hygrothermal simulation provides more detailed and accurate information on the risk of moisture problems within building components and on the design of remedial treatment. While the Glaser method considers only steady-state conduction of heat and vapour diffusion, the transient hygrothermal simulation models which are composed of the formulae defined in this document also take account of heat and moisture storage, latent heat effects and liquid and convective transport under realistic boundary and initial conditions. The application of such models has become widely used in building practice in recent years, resulting in a significant improvement in the accuracy and reproducibility of hygrothermal simulation.

The following examples of transient heat and moisture phenomena in building components can be simulated by the models covered in this document:

- drying of initial construction moisture;
- moisture accumulation by interstitial condensation due to diffusion in winter;
- moisture penetration due to driving rain exposure;
- summer condensation due to migration of moisture from outside to inside;
- outside surface condensation due to cooling by long-wave radiation exchange;
- moisture-related heat losses by transmission and moisture evaporation.

# Internal Wall Insulation Systems

# Wall Preparation

- Investigate for Damp Penetration Issues
- Assess for Salt Penetration
- Determine the type of existing plaster
- Strip Back Impervious materials and restore the wall surface

## How to prepare traditional solid walls for IWI Installation

### Best Practices

For optimal performance and longevity of any internal wall insulation system, it is crucial to eliminate or decrease all sources of moisture in the wall before installation begins. Persistent damp penetration issues in the wall construction could potentially cause harm to the insulation system or the structure of the building and must all be thoroughly investigated.

Effective ventilation of the living space is also essential both during the refurbishment period when wet trades may be employed and over the lifetime of the building to maintain a healthy, comfortable, and durable living space.

Once an insulation system is installed, it is important to undertake regular maintenance of the building to ensure moisture related issues do not reoccur.

**Please note:** Buildings which are prone to flooding are outside the scope of this guidance document. Additional guidance can be found here: [Historic England – Flooding and Historic Buildings](#).

### What to investigate:

- Suitability of the building
- Existing finishes on the wall
- Condition of the wall
- Weatherproofing
- Drainage & Ground source damp
- Pipes (internal plumbing & external water goods)

### Suitability of the building

The building should be assessed to ensure that it is suitable for insulation. This should consider external ground levels, runoff patterns, the water table, the existence of a functioning damp-proof course and if external drainage such as a French drain are present. If the walls being insulated are below ground level and penetrating damp cannot be addressed from the outside, a waterproofing system such as [Diasen Watstop](#) should be installed prior to the internal wall insulation.

### Existing finishes on the wall

The following coverings must be removed from the wall:

- Plastic based paints
- Wallpaper

Impervious coverings like these impede the overall breathability of the wall and can trap moisture inside the wall preventing evaporation. This can lead to moisture accumulation, mould growth, structural damage and poor indoor air quality. They can be removed with scrapers, sandblasters, vapour blasters or a wallpaper stripper.

Once coverings are removed, investigate what type of plaster is present on the walls (if any) to ensure it is compatible with the proposed insulation system.

# Wall Preparation

Remove any **impervious coatings** from the interior surface first

- gypsum plasters
- hard cement plasters\*\*\*
- glossy paints
- wallpapers

Note: Lime plaster (*if stable*) is fine

## Points to consider prior to specifying IWI Systems

Look before you leap!

- **Wall depth?**
- **Stone/Brick type?**
- **Exposure (driving rain)?**
- **Existing damp penetration?**
- **Existing external/Internal plaster?**
- **Plaster type both internally and externally?**
- **Thermal Bridging?**
- **Other points (airtightness, ventilation, etc)**

# Internal Insulation Of Solid Walls

1. Directly rendered natural insulation systems (Gutex woodfibre – hygroscopic material)
2. Mineral based capillary active insulation systems
  - Calcium silicate board (Calsitherm)
  - Insulating plaster (Diathonite)
3. Timber stud full filled with natural insulation with intelligent membranes

# What is a Hygroscopic material?

Having a tendency to  
capture water molecules  
from the air  
through absorption

Ref: [www.hygro.geroldinger.com](http://www.hygro.geroldinger.com)

When **dry rice** is exposed to air with high relative humidity (RH) the rice grains will **absorb water** from the air

When **wet rice** is exposed to air with low RH the rice grains will **release water** to the air (drying).

## Hygroscopic IWI Insulation

Typical U-values for solid brick or stone walls.

Wall Type	Diathonite Levelling Plaster (mm)	Wood Fibre Thickness (mm)	U-value (W/m <sup>2</sup> K)
220mm (brick)	--	--	2.19*
220mm (brick)	20mm	40	0.49
220mm (brick)	20mm	60	0.39
220mm (brick)	20mm	80	0.32
220mm (brick)	20mm	100	0.28
500mm (stone)	--	--	2.38*
500mm (stone)	30mm	40	0.44
500mm (stone)	30mm	60	0.36
500mm (stone)	30mm	80	0.30
500mm (stone)	30mm	100	0.26

\* uninsulated wall

If standard lime plaster is used (instead of Diathonite) with 60mm of Thermoroom, the U-value is 0.49W/m<sup>2</sup>K. With Diathonite, it is 0.36W/m<sup>2</sup>K.

DESIGN • BUILD • FITOUT

# What you need

Lime plaster or Diathonite (leveling coat), ~20mm

GUTEX adhesive, ~5mm

Gutex Thermoroom woodfibre boards, 40/60/80/100mm

Lime Green SOLO one-coat finishing plaster, 10mm

Accessories (corner beads, mesh, sealing strips etc)

## Case Study 2

Block M, Dublin Castle

## Block M Dublin Castle – Hillfort Plastering

A company of the  
CALSITHERM® group

# Calsitherm Calcium Silicate Board - Main Attributes

- High thermal resistance ( $\lambda=0,059\text{W/mK}$ )
- Capillary active & diffusion-open
- Mould inhibiting (high Ph value)
- Non-combustible
- Dimensionally stable, self-supporting, & compression-resistant
- Quick and easy to install
- Harmless to the environment and health
- Pest-resistant

# Thermoroom vs Calsitherm vs Diathonite

# Thermoroom vs Calsitherm vs Diathonite

## Calsitherm - capillarity

## When is capillary active insulation most important?

In extreme cases...

- Existing wall is very **thick** or very **thin** brickwork
- Very **exposed** to driving rain
- **Low capillarity** on internal surface (i.e. existing internal cement render which can't be removed)
- Mortar **joints** are very small
- Existing stone very hard & **vapour resistant** (e.g. Slate, Granite, Hard Limestone)

# Dublin Civic Trust 18 Ormond Quay

# Detailing matters

# Sustainable Retrofit in Practice:

## Case Study : Main St Cloughjordan

### Other Works included

- Reclaimed timber floors & doors
- 40mm cork lime render at external walls
- 200mm woodfibre insulation under rafters
- 150mm cellulose insulation at intermediate floors
- Reuse of fibreglass & mineral wool in floors
- Passive windows & rooflights to north facade (soon front/south windows, doors & shopfronts)
- Airtightness taping at all windows & junctions from first floor up
- Proclima Intello diffusion membrane at roof
- New natural slates replacing fibre cement

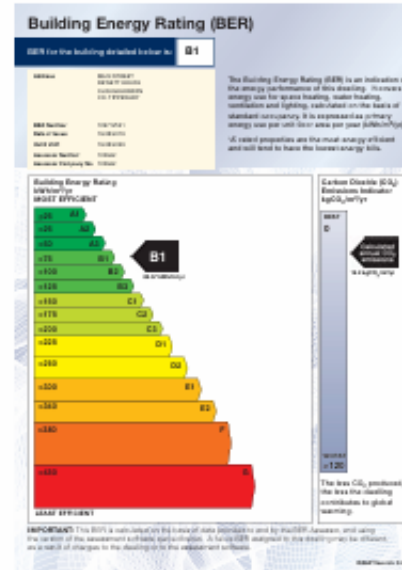

# Sustainable Retrofit in Practice: Case Study : Main St Cloughjordan

## NUMBERS : ENERGY

## ENERGY PERFORMANCE

- Heat Loss indicator (HLI)
  - Estimated preworks =  $3.48 \text{ W/m}^2/\text{K}$
  - Projected after works =  $1.85 \text{ W/m}^2/\text{K}$
  - Using DEAP we projected  $1.6 \text{ W/m}^2/\text{K}$
- Original BER rating at G, 2018 assessment put it at B1 ( $82.37 \text{ kWh/m}^2/\text{yr}$ ) and we are aiming for A3 when complete
- **In reality, it's already better!**
  - Electricity bills indicate we used  $10,834 \text{ kWh}$  for period 10/2020 to 10/2021
  - With floor area of  $250 \text{ m}^2$  –  $10834/250 = 43 \text{ kWh/m}^2/\text{yr}$
  - This is A2 performance (despite 8 months of overheating for my mother's apartment)
- Heat pump on automatic 24 hours/day
- constant temperature at 20 degrees
- energy supply is from renewable source

# How much is enough?

ASBP Briefing Paper - June 2024

## Insulation and retrofit: Finding the sweet spot

### The retrofit challenge

The UK's 29m homes are among the least energy-efficient in Europe with approximately two-thirds in need of better insulation levels<sup>1</sup>. This includes 8.5 million difficult to treat 'solid wall' homes with over 90% of these currently uninsulated<sup>2</sup>. Improving the energy efficiency of our housing stock is vital if we are to meet our net zero commitments.

Building Regulations throughout the UK provide flexibility on target U-values in existing buildings. For example, Part L<sup>3</sup> of the Building Regulations for England (p26) offers some flexibility when retrofitting existing walls, roofs and floors.

An improved U-value of 0.30 W/(m<sup>2</sup>·K) is the target but a 'threshold' level of up to 0.70 W/(m<sup>2</sup>·K) is sufficient for walls, as long as the approach can achieve a simple payback not exceeding 15 years and is 'technically and functionally feasible'.

This lesser standard for the thermal element (U-value) is acceptable where retrofit measures seek to balance the requirements of Part C of the Building Regulations (England) to protect from the harmful effects of interstitial and surface condensation, which can lead to mould growth.

English Housing Survey data<sup>4</sup> published in July 2023 found that damp and mould affect 177,000 social homes. The effects of exposure to mould can be life-threatening, most recently amplified in the tragic case of Awaab Ishak<sup>5</sup>.

## Conclusions

- Demonstrates that architectural/conservation concerns can be addressed alongside ambitious energy/carbon reduction targets
- Walls were made more moisture open through replacement of cement pointing with capillary active cork lime thermal plaster and plastic paints replaced with mineral paints
- Historic buildings can perform very well, using measures that fit comfortably with their original building physics and architecture.
- A combination of very good fabric measures and contemporary low-carbon heating can work together successfully and in a genuinely complementary way.
- Targeting super low U values is not necessary to attain high levels of comfort and energy performance.
- This demonstration suggests that there is real hope that hundreds and thousands of 'traditional' homes in the UK & Ireland can be upgraded responsibly, and in a genuinely sustainable manner.
- In order to reach this range, it first requires a 'good' fabric first approach.
- Architectural ambition can and should go hand in hand with 'carbon counting'. Both have a crucial part to play in making places and spaces that will stand the test of time and become truly sustainable.

# Conclusions

1. Do not get blinkered by U value!! **0.27W/m<sup>2</sup>K for IWI can significantly increase moisture risk**
2. Hygrothermal simulation a key decision support tool to deliver robust long term solutions for IWI on solid masonry walls
3. Unrendered brick walls particularly prone to hygrothermal issues (thermal bridges, joist ends and consider insulation depth)
4. Wall thickness a key consideration, thinner walls more prone to moisture fluxes
5. We would not recommend using VCL's on externally unrendered, unprotected walls, especially in exposed areas
6. Where VCL's are used they must be "Intelligent hydrosafe membranes" and their integrity is critical. Validate with Blowerdoor!
7. Careful Wall preparation essential prior to insulating (remove gypsum, wallpaper etc)
8. Installers should receive adequate training
9. Ensure materials are carefully verified and at very least have relevant DOP or some form of 3<sup>rd</sup> party certification and clear disclosure of performance characteristics
10. A Dublin solution is not representative of the whole of Ireland. Driving rain varies significantly from Belmullet to Dublin.
11. SEAI pilot programme opens the door to assess best practice approaches to sensitively retrofit traditional buildings, but shouldn't stop there, this is essential for all traditional buildings
12. A balance can be struck to improve thermal performance of traditional buildings and protect our heritage.
